

Proof companion

Coupling-gated cortical coherence

A companion to the repository's Lean development

Second coverage stage: 17 September 2026

Abstract

This document presents mathematical explanations of 129 selected Lean results from 7 source modules. It places the assumptions and the argument of each result beside an appendix generated from Lean's elaborated statements. The saved extraction also contains 4973 nested tactic records, their before/after goal states, proof dependencies, and the fields of project structures reached through statement types. The mathematical prose is an editorial draft checked against the source during preparation; Lean verifies the formal proofs, not this prose.

B Two extracted physical obligations 61

1 Reading and auditing the companion

The explained arguments are of six kinds: exact and approximate gluing, the critical exponent of stationary coherent solutions, the conditional composition of the framework, the witnesses and counterexamples that fence that composition, a no-go for the vertex-supported kernel beside the cell-pair construction that avoids it, and a concrete nonconstant family. The selection is explicit in `selection.json`. Each of its declarations has an extracted statement in the appendix, including implicit type and instance parameters. Definitions and hypotheses abbreviated in the mathematics are spelled out where they carry substantive content.

The selection follows a stated rule rather than a list of favourites. Three modules --- the chain and the two analytic results it consumes --- are covered *completely*: every theorem they declare has an extracted statement here, so a reader can see what those modules contain and not only what the prose chose to discuss. The finite-measure gluing module is covered completely on the same rule. Three further modules contribute selected witnesses and convergence results. Coverage of the rest of the development remains selected, and the coverage table records exactly which declarations are present.

The prose groups rewrites and elementary algebra into mathematical steps. Full tactic histories remain in the JSON snapshots under `data/`; Section 7.1 displays a small actual trace. A

nested tactic record is an elaboration event, so its count includes wrappers and macro expansions. It is not a count of independent mathematical steps.

Three distinctions guide the reading. A theorem can depend on physical conditions supplied as structure fields. A formally valid conditional theorem can have hypotheses that require separate witnesses. A dependency on a named definition does not establish an empirical interpretation of that definition. The examples below keep these distinctions visible.

The extractor rejects elaboration errors and checks that each selected result's axioms are drawn only from `propext`, `Classical.choice`, and `Quot.sound`. This is a check of logical dependencies. It does not remove the hypotheses in the statement or the obligations carried by its structures.

2 Exact and approximate gluing

2.1 The sheaf used by the development

Let X be a topological space with the measurable and Borel structure required by the formal statement. Let F_0 assign to an open subset its finite spatial measures, with restriction maps. The Lean definition `probabilityPresheaf` denotes the sheafification F of F_0 . Despite that identifier, the initial local data are unnormalised finite measures; mass one is not part of this definition.

Claim 2.1. *F is a sheaf.*

Proof. Sheafification returns a sheaf together with its sheaf-property proof. Projecting that proof establishes the claim for F . $\square$

Extracted Lean statement: Appendix A.1.

Scope. This result uses the sheafification construction. It supplies no physical mechanism for producing compatible local data.

2.2 Compatible local sections have a unique extension

Claim 2.2. *Let F be any sheaf of types on X , and let $(U_i)_{i \in I}$ be an open cover of X . Suppose $s_i \in F(U_i)$ and*

$$s_i|_{U_i \cap U_j} = s_j|_{U_i \cap U_j} \quad (i, j \in I).$$

Then exactly one $g \in F(X)$ satisfies $g|_{U_i} = s_i$ for every i .

Proof. The unique-gluing form of the sheaf condition gives a section on $\bigcup_i U_i$, with the specified restrictions, unique among sections there. The cover equality identifies that union with X . Transport the section along this equality. Functoriality of the restriction maps shows that its restriction to each U_i is s_i .

Conversely, transport any competing section on X back to the union. Its restrictions are again the s_i , so the uniqueness supplied by the sheaf condition identifies it with the first section. Transporting forward gives the required equality on X . In the Lean proof, equality of the relevant inclusion maps uses the fact that morphisms between opens form a subsingleton. $\square$

Extracted Lean statement: Appendix A.2.

Claim 2.3. *The same conclusion holds for the development's sheafified spatial measures.*

Proof. Apply the preceding claim to $F = \text{probabilityPresheaf}$ and use the sheaf property established above. The compatible family and cover equality are exactly the hypotheses of this application. $\square$

Extracted Lean statement: Appendix A.3.

Scope. This proof is a direct term applying a previous theorem. It has no tactic history; the extracted statement and proof dependencies still cover it.

2.3 What equilibrium contributes

A thermodynamic cover supplies local sections s_i , phases θ_i , and a finite, symmetric, strictly positive coupling matrix. Its structure includes two substantive conditions: the phase configuration globally minimises the reduced Kuramoto potential, and

$$\cos(\theta_i - \theta_j) = 1 \implies s_i|_{U_i \cap U_j} = s_j|_{U_i \cap U_j}.$$

The second condition is an obligation on the supplied local data.

Claim 2.4. *A thermodynamic cover determines a unique global section with its prescribed local restrictions.*

Proof. The theorem characterising global minima of the reduced Kuramoto potential implies phase locking for the cover: $\cos(\theta_i - \theta_j) = 1$ for every pair. The overlap-agreement field then makes the local sections compatible. Apply the spatial-measure gluing theorem to the cover and that compatible family. $\square$

Extracted Lean statement: Appendix A.8.

Scope. This argument consumes the supplied equilibrium and overlap conditions. The existence of a physical system satisfying them is a separate matter.

2.4 When the section represents an actual finite measure

Let $(U_i)_{i \in I}$ be a finite measurable cover of X and let μ_i be finite measures, extended by zero outside their patches if necessary. Assume

$$\mu_i|_{U_i \cap U_j} = \mu_j|_{U_i \cap U_j} \quad (i, j \in I).$$

These are equalities of actual measures, before sheafification.

Claim 2.5. *There is a unique finite measure ν whose restriction to each U_i is $\mu_i|_{U_i}$.*

Proof. Order the finite index set and put $D_i = U_i \setminus \bigcup_{j < i} U_j$. The D_i are measurable, disjoint, cover X , and satisfy $D_i \subseteq U_i$. Define $\nu = \sum_i \mu_i|_{D_i}$, a finite sum of finite measures. On $U_k \cap D_i$, overlap agreement identifies μ_i with μ_k . Thus $\nu|_{U_k} = \sum_i \mu_k|_{U_k \cap D_i} = \mu_k|_{U_k}$. Two measures with these restrictions agree on the covering pieces, hence are equal. $\square$

Extracted Lean statement: Appendix A.122.

Claim 2.6. *If a thermodynamic cover's local sections are the sheaf images of such compatible finite measures, its glued section is the image of ν .*

Proof. The sheafification map preserves restrictions. The equality of actual measure restrictions therefore makes the image of ν restrict to every supplied local section. Uniqueness of the sheaf gluing identifies this image with `ThermodynamicCover.invariantMeasure`. $\square$

Extracted Lean statement: Appendix A.24.

Scope. The cover already has a finite patch index. Compatible finite-measure representatives are explicit additional data; no general inverse to sheafification is assumed. Local finite measures can always be extended by zero to the ambient space and recovered on their patches (measureOnOpen_map_subtype). No mass-one normalization is imposed.

On the real line, the patches $(-\infty, 1)$ and $(-1, \infty)$ carry $\delta_{-2} + \delta_0$ and $\delta_0 + \delta_2$, respectively. They agree on the overlap, and their unique extension is $\delta_{-2} + \delta_0 + \delta_2$, with total mass three.

Extracted Lean statement: Appendix A.124.

Extracted Lean statement: Appendix A.125.

By contrast, singleton patches at every natural number, each requiring mass one, have no finite-measure extension: any such measure would equal counting measure, whose total mass is infinite.

Extracted Lean statement: Appendix A.123.

2.5 Approximate agreement gives a controlled selection

Let the site set and patch index set be finite. Let $s_i(x) \geq 0$ be local mass profiles represented as functions on the ambient sites. Let $w_i(x) \geq 0$ satisfy $w_i(x) = 0$ outside U_i and $\sum_i w_i(x) = 1$ at every site. Assume that for $x \in U_i \cap U_j$, $|s_i(x) - s_j(x)| \leq \varepsilon$, where $\varepsilon \geq 0$.

Claim 2.7. *The selected profile $g(x) = \sum_j w_j(x)s_j(x)$ satisfies $\sup_{x \in U_i} |g(x) - s_i(x)| \leq \varepsilon$ for every patch i .*

Proof. Fix $x \in U_i$. Every nonzero weight $w_j(x)$ has $x \in U_j$, so its profile is within ε of $s_i(x)$. Normalisation and the triangle inequality therefore give

$$|g(x) - s_i(x)| = \left| \sum_j w_j(x)(s_j(x) - s_i(x)) \right| \leq \sum_j w_j(x)\varepsilon = \varepsilon.$$

The terms with zero weight contribute zero. The uniform metric on the finite patch converts these pointwise bounds into the displayed profile-distance bound. Lean isolates the weighted inequality in its helper `weighted_dist_le` and then applies it at each site. $\square$

Extracted Lean statement: Appendix A.15.

Scope. The profiles need not have total mass one. The result provides an approximation in the specified uniform mass metric, and assumes the overlap bounds and the subordinate normalised weights.

3 The stationary critical exponent

Write

$$E(a) = \frac{\int_0^{2\pi} \sin^2 \theta e^{a \cos \theta} d\theta}{\int_0^{2\pi} e^{a \cos \theta} d\theta}.$$

This is `vonMisesSRatio`. Its denominator is strictly positive.

3.1 The second-order expansion

Claim 3.1. As $a \rightarrow 0$,

$$E(a) = \frac{1}{2} - \frac{a^2}{16} + o(a^2).$$

Proof. The previously proved differentiability results give $E \in C^2$, $E(0) = 1/2$, $E'(0) = 0$, and $E''(0) = -1/8$. Taylor's theorem with a little-o remainder yields $E(a) = E(0) + E'(0)a + E''(0)a^2/2 + o(a^2)$. Substituting those values gives the claimed polynomial. The Lean proof applies the general Taylor theorem, identifies its second iterated derivative using the derivative lemmas, and simplifies its Taylor polynomial. $\square$

Extracted Lean statement: Appendix A.41.

Scope. The asserted remainder is $o(a^2)$. This statement supplies no fourth-order remainder estimate.

3.2 An arbitrary family approaching threshold

Claim 3.2. Let $D > 0$, let ℓ be a filter on an index type, and let K_x, r_x be real-valued functions on that type. Suppose $K_x \rightarrow 2D$, $r_x \rightarrow 0$ along ℓ , and eventually

$$K_x > 2D, \quad r_x > 0, \quad r_x = \text{selfConsistency}(K_x, D, r_x).$$

Then $r_x^2/(K_x - 2D) \rightarrow 1/D$ along ℓ .

Proof. Set $a_x = K_x r_x / D$ and write

$$E(a) = \frac{1}{2} - \frac{a^2}{16} + a^2 q(a).$$

The previous expansion gives $q(a) \rightarrow 0$ as $a \rightarrow 0$, taking the quotient with Lean's totalised division at zero. The assumed limits imply $a_x \rightarrow 0$, hence $q(a_x) \rightarrow 0$.

For an index satisfying the eventual hypotheses, positivity gives $a_x \neq 0$ and $K_x - 2D \neq 0$. The previously proved reformulation of the self-consistency equation gives $E(a_x) = D/K_x$. Substituting the expansion and rearranging yields

$$K_x - 2D = K_x a_x^2 (1/8 - 2q(a_x)), \quad \frac{r_x^2}{K_x - 2D} = \frac{D^2}{K_x^3 (1/8 - 2q(a_x))}.$$

The denominator in the last expression tends to $(2D)^3/8 = D^3 > 0$. The quotient therefore tends to $D^2/D^3 = 1/D$. The equality of the quotients holds eventually, which transfers this limit to the desired expression. $\square$

Extracted Lean statement: Appendix A.42.

Scope. Convergence to zero and eventual stationarity are hypotheses. This general statement allows the bottom filter, where its eventual and convergence conditions are vacuous. A concrete branch supplies the substantive application below. The claim establishes stationary asymptotics, with no time evolution or stability conclusion.

3.3 A branch that satisfies the hypotheses

For $D > 0$ and $K > 2D$, define $r_*(D, K)$ by choosing the coherent solution from the theorem that proves existence and uniqueness in $(0, 1]$. The Lean function `coherentBranch` uses this choice in that regime and returns zero outside it.

Claim 3.3. *If $D > 0$ and $K > 2D$, then $0 < r_*(D, K) \leq 1$ and*

$$r_*(D, K) = \text{selfConsistency}(K, D, r_*(D, K)).$$

Proof. The two inequalities on D, K select the positive branch of the definition. The specification of the chosen witness is exactly positivity, the bound by one, and the fixed-point equation supplied by the existence theorem. $\square$

Extracted Lean statement: Appendix A.43.

Claim 3.4. *For fixed $D > 0$, as K decreases to $2D$ through $K > 2D$,*

$$\frac{r_*(D, K)^2}{K - 2D} \longrightarrow \frac{1}{D}.$$

Proof. Apply the family theorem to the right-hand neighbourhood filter of $2D$, with the identity function for K . The previously proved `coherentBranch_tendsto_zero` supplies the limit of r_* at the threshold. Membership in the right-hand neighbourhood gives $K > 2D$ eventually, and the branch specification supplies positivity and stationarity there. These are all the hypotheses of the family theorem. $\square$

Extracted Lean statement: Appendix A.45.

Scope. The approach filter on the real line is nontrivial, and the branch provides actual coherent solutions. This removes the vacuity issue in this application. The conclusion still concerns stationary solutions.

4 What the conditional chain composes

The chain uses a common topological and measured substrate, its sheaf of global sections, a supplied complete metric on those sections, a neural field, a thermodynamic cover T , and a reflexive boundary with prediction map P . The precise type and instance parameters are printed in the appendix.

4.1 The common downstream argument

Suppose a sequence of energies coarse-grains to L , the elapsed parameter τ is positive, and the following named implications hold:

- *E56:* coarse-graining implies $D > 0$, $K \geq 0$, $L = K$, and an identification of the supplied field with the parameters K, D .
- *E67:* those scalar conditions imply $K > 2D$.
- *E78:* a coherent order parameter implies that the supplied cover is reached by the specified relaxation at a coupling at least K .
- *E89:* that reachability supplies a section s which restricts to the local data of T , is fixed by P , and comes with the stated Lipschitz bound on P at $\text{resonanceRate}(K, D, \tau)$.

Claim 4.1. *There is a global section compatible with a thermodynamic cover which is the unique fixed point of the prediction map.*

Proof. Apply *E56* to the coarse-graining hypothesis and *E67* to its scalar conclusion. The supercritical existence theorem supplies a coherent order parameter. Apply *E78* and then *E89* to obtain the section s , its local restrictions, the Lipschitz bound, and $P(s) = s$.

The section s makes the space of global sections nonempty. The theorem `self_of_coherent_order_parameter`, using completeness, the Lipschitz bound, coherence, and $\tau > 0$, applies the contraction argument to obtain a unique fixed point p . Since s is fixed, uniqueness gives $s = p$. Every fixed point t equals p and hence s . Pair s with the supplied cover T and its known restriction equations. This is exactly the predicate `UnifiedSelf`. $\square$

Extracted Lean statement: Appendix A.69.

Scope. The identity between the glued section and a fixed section is supplied in *E89*; the contraction argument proves uniqueness. The concrete-field conjunct of *E56* is retained as an input constraint but is not used by this proof's downstream fixed-point argument. The source also establishes a local `Unity` fact which the concluding construction does not reference. Its constants can still occur in the unnormalised proof term; a syntactic dependency list alone therefore does not identify minimal premises.

4.2 The passive composition

The passive chain additionally supplies a finite nonempty register, its statistical-mechanics instance and update, a field and vacuum set, and measurable carrier types for predictive information. Its remaining named implications are:

- *E12*: the capacity bound implies that the field leaves the vacuum set.
- *E23*: leaving that set implies the register update is not surjective.
- *E34*: dissipation supplies a predictive-dissipation structure whose thermal scale and dissipated work match the register's temperature and heat, and whose nonpredictive information is strictly positive.
- *E45*: the predictive bound implies the chosen coarse-graining statement.

Claim 4.2. *Under *E12* through *E89* and the stated structural hypotheses, the passive chain concludes `UnifiedSelf` for the supplied reflexive boundary.*

Proof. Finiteness gives the capacity bound. Apply *E12* to obtain vacuum departure, then *E23* to obtain a nonsurjective update. The proved dissipation theorem, using the supplied statistical-mechanics structure, gives positive heat. Apply *E34* and retain its predictive-dissipation witness R . The bound associated with R gives the predictive node. Apply *E45* to obtain coarse-graining and then invoke the downstream claim with *E56* through *E89*. $\square$

Extracted Lean statement: Appendix A.70.

Scope. The eight named implications remain hypotheses. Conditions inside the statistical-mechanics, thermodynamic-cover, and other structures are additional obligations. The equalities and positivity in *E34* constrain which witness is admitted, while the passage through *E45* uses its predictive structure. The conclusion has no predicate asserting experience or biological implementation.

5 That the chain is not vacuous, and what it still does not say

Both chain theorems are conditional: each accepts eight named implications and concludes `UnifiedSelf`. A conditional theorem whose hypotheses nothing satisfies proves nothing about anything, so the development supplies witnesses discharging all eight at once, and --- separately --- counterexamples showing that the same hypotheses cannot be met by substituting an arbitrary target.

5.1 All eight arrows in one composition

Claim 5.1. *There are a double well, an absorbing register, an erasing update, a refining mesh, and a field and cover over the type `Cortex` that satisfy `E12` through `E89` simultaneously; hence `UnifiedSelf` holds for the supplied reflexive boundary.*

Proof. Apply the passive chain to those components. The first four arrows are supplied by their witnesses; `E56` is discharged by the numerals $D = 1$, $K = 3$, $L = 3$ together with the identification of the supplied field, `E67` by evaluating the critical coupling and comparing $3 > 2$, `E78` by the cover's reachability at coupling three, and `E89` by the constructed section, its restriction equations, the Lipschitz bound and the fixed-point equation. $\square$

Extracted Lean statement: Appendix A.95.

Scope. The components are separate toy constructions with different state spaces. The field, cover and reflexive boundary share the three-site substrate. Their simultaneous satisfaction establishes that the hypotheses are consistent, and identifies no physical mechanism common to a double well, a register, a mesh and a cortical cover. In particular nothing here interprets `Cortex` as `cortex`.

5.2 Four active branches, not one

The active chain replaces the passive predictive node with a heat-budget node. The development discharges its hypotheses with four arrangements: with a noisy actuator, with that actuator held to a named register budget, with a process-dependent actuated field, and with a kernel built from mode occupancies on a product space.

Extracted Lean statement: Appendix A.106.

Extracted Lean statement: Appendix A.109.

Extracted Lean statement: Appendix A.114.

Extracted Lean statement: Appendix A.120.

Scope. The register-budget arrangement changes `E34Active`: its heat allocation is derived from the register's ledger. The actuated and microscopic arrangements change `E45Active`, the arrow feeding coarse-graining, using process-dependent spatial energies. All four retain the same downstream field, cover and boundary. They demonstrate several ways to satisfy the hypotheses; they do not identify one common physical mechanism.

5.3 The obligations are not free

Two kinds of rejection fence the active node. The first concerns the budget.

Claim 5.2. *The actuator does not satisfy `ActiveBound` at budget 0.*

Proof. `ActiveBound` requires the process's cost to lie below the budget. The actuator's cost is positive, and a positive real is not at most zero. $\square$

Extracted Lean statement: Appendix A.103.

The second concerns the limit. Each convergence arrow says that, *given* the bound, a named energy sequence tends to a named target. Since the bound genuinely holds for these processes, the arrow can be applied, and the target is then pinned by uniqueness of limits.

Claim 5.3. *The active convergence arrow fails for the constant-zero energy sequence at target 3; for the actuated sequence at target 0; and for the microscopic sequence at target 0. The passive arrow likewise fails for the remembered sequence at target 0.*

Proof. In each case supply the arrow with the bound that does hold, obtaining convergence of the sequence to the stated target. The same sequence is already known to converge --- the constant sequence to 0, the others to their computed spatial limits. Uniqueness of limits in $\mathbb{R}$ equates the two values, and the resulting numerical identity is false. $\square$

Extracted Lean statement: Appendix A.104.

Extracted Lean statement: Appendix A.113.

Extracted Lean statement: Appendix A.116.

Extracted Lean statement: Appendix A.119.

Scope. These are rejections rather than vacuous implications precisely because the premise is inhabited in each case. They show that the convergence arrows constrain which energy sequence and which limit may be supplied; they do not show that any particular sequence is the physically correct one. Choosing it remains a modelling obligation outside the theorem.

5.4 The passive edge does not pick out its hardware

Claim 5.4. *Two different declared systems over the same joint law --- one retaining its memory, one scrambling it --- discharge the identical passive convergence edge.*

Proof. Each supplies the joint law that the edge's construction requires, and the convergence itself is the same spatial fact about the shared energy sequence. Neither proof consults the system's efficiency. $\square$

Extracted Lean statement: Appendix A.117.

Extracted Lean statement: Appendix A.118.

Scope. The edge is therefore insensitive to how well the hardware preserves what it stores. No configuration law, partition or efficiency is selected by discharging it, which bounds how much the passage through this node can be read as a claim about physical implementation.

6 The vertex-supported obstruction and the cell-pair construction

The scalar mesh-refinement theorem does not reconstruct a continuum kernel. Its vertex-supported candidate contributes zero to the continuum coupling functional on an atomless substrate. This obstruction concerns that particular representation. The development also provides a cell-pair construction which converges to a specified continuous kernel.

6.1 The target structure constrains nothing

A `ContinuousNeuralField` over a substrate M carries a drift $\omega : M \rightarrow \mathbb{R}$, a kernel $K : M \times M \rightarrow \mathbb{R}$, and a timescale $\tau \in \mathbb{R}$, with no conditions relating them.

Claim 6.1. *For any ω , K and τ whatsoever, a `ContinuousNeuralField` over M exists.*

Proof. The three data are exactly the structure's fields, so the anonymous constructor supplies the required inhabitant. $\square$

Extracted Lean statement: Appendix A.96.

Scope. A constructor taking a mesh to such a field would therefore typecheck with a kernel unrelated to that mesh, and its proof would be a definitional unfolding. The statement records that the edge would carry no information, not that a limit fails to converge.

6.2 The candidate kernel does carry the weights

Write emb for a triangulation's vertex embedding into M and w for its edge weights. The induced kernel places each weight at its embedded pair,

$$\text{vertexKernel}(x, y) = \sum_u \sum_v [x = \text{emb } u \wedge y = \text{emb } v] w(u, v),$$

and vanishes off the image of the vertex set.

Claim 6.2. *The kernel is sited on the finite set $\text{emb}[V]$: if $x \notin \text{emb}[V]$ then $\text{vertexKernel}(x, y) = 0$ for every y .*

Proof. Fix such an x and any y . Every summand carries the condition $x = \text{emb } u$; were it met for some u , x would lie in the image. So each summand is zero, and both sums vanish. $\square$

Extracted Lean statement: Appendix A.97.

Claim 6.3. *If emb is injective, then $\text{vertexKernel}(\text{emb } u, \text{emb } v) = w(u, v)$.*

Proof. Injectivity makes $\text{emb } u = \text{emb } b$ fail for $b \neq u$, so the outer sum reduces to its u th term, and the inner sum to its v th by the same argument. That term is $w(u, v)$. $\square$

Extracted Lean statement: Appendix A.98.

Scope. This is what stops the next result from being a statement about a kernel that was zero from the outset. At embedded pairs the kernel takes precisely the value the triangulation assigns.

6.3 The no-go

The field results are stated through the coupling functional

$$\text{fieldCorrelation}(\mu, \theta, K) = \int_M \left(\int_M K(x, y) \cos(\theta(y) - \theta(x)) d\mu(y) \right) d\mu(x).$$

Claim 6.4. *On a substrate whose measure has no atoms, $\text{fieldCorrelation}(\mu, \theta, \text{vertexKernel}) = 0$ --- for every weight assignment and every phase field.*

Proof. By the siting claim the inner integral vanishes for each x outside the finite set $\text{emb}[V]$. A finite set is a finite union of singletons, and no singleton carries mass, so that set is null. The outer integral of a function supported in a null set is zero. $\square$

Extracted Lean statement: Appendix A.99.

Scope. The weights are unconstrained and the phase field is arbitrary, so no choice of triangulation data evades the conclusion. The obstruction is that the discrete data occupies a null set, not that the weights are small.

6.4 What this locates

The coarse-graining theorem converges a discrete coupling *energy* --- one real number per triangulation --- to an integral over the substrate, and the edge-weight sum reaches the same scalar. Both integrate the pair structure away, while a continuum kernel is a function of two points. Spreading the weights over cells rather than vertices would require a product-structured decomposition of $M \times M$; the triangulation's edge regions are subsets of M alone.

6.5 The positive construction and its input

KernelMesh supplies a finite measurable partition and one sample per cell. It extends each sampled pair value over the whole cell pair. KernelMesh.kernel_tendsto proves pointwise convergence to a supplied continuous kernel when the samples approach their points; KernelMesh.energy_tendsto passes the limit through the integral under compactness, second countability and finite measure. The microscopic actuator provides one such kernel from declared mode profiles and occupancies. These results are in Phase2_KernelMesh.lean and Phase3_LocalActuator.lean. The cell-pair integral identity and the two convergence results are included in the extracted appendix.

Extracted Lean statement: Appendix A.127.

Extracted Lean statement: Appendix A.128.

Extracted Lean statement: Appendix A.129.

Scope. The vertex-supported no-go does not obstruct this cell-pair construction. Its limiting kernel is specified by the hardware model, rather than inferred from a scalar energy alone. The chain receives a concrete field through E56, whose kernel conditions constrain the admissible input. The downstream fixed-point proof uses only the scalar part of E56; the field conditions are consumed separately by em_field_exhibits_phase_transition. Identifying that field with cortex remains a physical modelling obligation.

7 A concrete nonconstant family and its trace

On the three-site type with sites left, mid, and right, the development defines the nonnegative mass profile

$$d_t = (\max(1 + \cos t, 0), 1, \max(2 + \cos t, 0)).$$

The use of max expresses Real.toNNReal; these are nonnegative spatial masses, without a normalisation requirement.

Claim 7.1. $d_0 \neq d_\pi$.

Proof. Suppose the profiles were equal. Evaluating at the left site would equate $\max(1 + \cos 0, 0) = 2$ and $\max(1 + \cos \pi, 0) = 0$, a contradiction. $\square$

Extracted Lean statement: Appendix A.121.

Scope. This witnesses nonconstant dependence on phase for this particular family. It does not assert that every thermodynamic cover has such dependence, or that this family models a biological substrate.

7.1 Before and after the actual tactics

The following excerpt is generated from the saved elaboration data for this proof. It selects the contradiction assumption, the evaluation at the left site, and the simplification that closes the goal. The complete nested records, including wrappers sharing source spans, remain in `data/witness.json`.

A Extracted statements and direct project dependencies

The following text is generated from elaborated Lean expressions. Universe parameter names, complete dependency lists including Mathlib, source excerpts, and goal states are retained in the JSON snapshots. Pretty-printing uses Lean's mathematical notation and can suppress implicit arguments at applications; the quantified hypotheses of the declaration remain in the displayed type. Dependency lists here show direct project constants in the proof term. They are not a minimal set of assumptions or a transitive explanation of every lemma.

B Two extracted physical obligations

These projection types are extracted from the structures used by the gluing results. They show the equilibrium and overlap-agreement obligations described in Section 2. The snapshots contain the other encountered structure fields as well. The exporter follows project statement types and parent fields; it does not claim a complete semantic expansion through every definition body or every Mathlib structure.
